About

The Document

In systems engineering approach, before doing anything with the design of the system under consideration, *requirements analysis* must be completed as one of the first tasks (if not the very first). Beginning with an itemized, atomic, classified and well defined list of requirements is essential. Because, following activities at various stages of development (like design coverage analysis, testing, verification, validation …) depend on the requirement specifications stated at the beginning.

RISC-V International provides the ISA (Instruction Set Architecture) and non-ISA requirement specifications for the RISC-V architecture (https://riscv.org/technical/specifications/). These documents in general are good written technical plain text documents. However, they lack some aspects of good requirement specification practices:

- Requirements are in free text form and not itemized: Itemized list of requirements enables requirement coverage in design, test, verification and validation phases.
- Text includes comments and information statements along with requirements: Statements must be clearly labeled and categorized.
- Some statements include more than one specifications: Each specification need to be isolated.
- Some specifications such as instruction definitions are distributed throughout the text: The distributed content need to be put together to have a complete the specification.

The aim of this document is providing an edited list of requirements for `RISC-V ABIs Specification, Document Version 1.0', Editors Kito Cheng and Jessica Clarke, RISC-V International, November 2022. github.com/riscv-non-isa/riscv-elf-psabi-doc. It is licensed under the Creative Commons Attribution 4.0 International License (CC-BY 4.0). https://creativecommons.org/licenses/by/4.0/

In particular:

- Statements were itemized and given an ID number.
- Each itemized statement was referenced to the original document to provide traceability
- Itemized statements were categorized
- Complex statements were broken into simpler atomic requirement statements when needed.
- Distributed requirement information was put together to form complete specifications.

Special attention was given to preserve original statements, even when dividing complex statements into simpler atomic statements. But occasionally, some statements were re-written as to form a formal requirement statement.

The Editor (or the systems engineer)

After 34 years of my career, I retired from my regular job in 2023. Now, I do part time consulting services to interested parties, while I do work on projects that interest me more than a regular work.

In my career I dealt with very diverse fields of engineering: Academics, C/C++ desktop programming, embedded systems, analog circuit design, DSP algorithms, VLSI/FPGA design, underwater acoustics are to name few.

I've always enjoyed designing controllers and processors with generic HDL for VLSI or FPGA. So, as my personal project to work on, I decided to design RISC-V cores with different capabilities.

Having some defense sector background, I find systems engineering approach very useful. After reading RISC-V specification documents, I decided to take the initiative and edit the documents into customer requirements list format which is a tough, tedious and time consuming work.

In case someone else could find these documents useful, I share them on github:
https://github.com/vizionerco/RISC-V

Best regards,

Mehmet Öner, Ph.D.

Table of Contents

Definitions

Table 1: Requirement Types

TYPE	NAME	EXPLANATION
H	Heading	Headings in the original document. Headings are included to provide context to the subsequent requirements
I	Information	These are statements that explain some aspects of the subject, but actually do not specify any requirement. For these types, the statement(s) in the text is given as is.
C	Comment	These statements are original comment statements in the RISC_V documentation which are explained as: “Commentary on our design decisions is formatted as in this paragraph. This non-normative text can be skipped if the reader is only interested in the specification itself.” For these types, the statement(s) in the text is given as is.
R	Requirement	These are statements that specify a specific need to be fulfilled. For these types, the statement(s) in the text is given as is where possible. In some cases, information is collected from different tables and figures to form a complete specification. In some cases, context is added in parenthesis to make the requirement self explanatory. In some cases, the statements are broken into single statements requirement statements.
O	Optional Requirement	These are tatements that specify a property that is not mandatory to implement. However if it is chosen to fulfill, it should obey this requirement. Inclusion of the text is the same as R/Requirement type.
T	Tentative Requirement	These are requirements but are not frozen yet by the RISC-V committee. Inclusion of the text is the same as R/Requirement type.

Table 2: Abbreviations & Definitions

SHORT	MEANING
ABI	Application binary interface
gABI	Generic System V Application Binary Interface
ELF	Executable and Linking Format
psABI	Processor-Specific ABI
DWARF	Debugging With Arbitrary Record Formats
GOT	Global Offset Table
PC	Program Counter
TLS	Thread-Local Storage
NTBS	Null-Terminated Byte String
XLEN	The width of an integer register in bits
FLEN	The width of a floating-point register in bits
Linker relaxation	A mechanism for optimizing programs at link-time

RISC-V Calling Conventions

CHAPTER 1 Register Convention

ID	REFERENCE	TYPE	DEFINITION
RVA.1.1	1.0 (p.6)	H	Register Convention
RVA.1.2	1.1 (p.6)	H	Integer Register Convention
RVA.1.3	1.1 (p.6) Table 1	R	Integer register convention

Name	ABI Mnemonic	Meaning	Preserved across calls?
x0	**zero**	Zero	- (Immutable)
x1	**ra**	Return address	No
x2	**sp**	Stack pointer	Yes
x3	**gp**	Global pointer	- (Unallocatable)
x4	**tp**	Thread pointer	- (Unallocatable)
x5 - x7	**t0 - t2**	Temporary registers	No
x8 - x9	**s0 - s1**	Callee-saved registers	Yes
x10 - x17	**a0 - a7**	Argument registers	No
x18 - x27	**s2 - s11**	Callee-saved registers	Yes
x28 - x31	**t3 - t6**	Temporary registers	No

RVA.1.4	1.1 (p.6)	R	In the standard ABI, procedures should not modify the integer registers **tp** and **gp**, because signal handlers may rely upon their values.
RVA.1.5	1.1 (p.6)	O	The presence of a frame pointer is optional. If a frame pointer exists, it must reside in x8 (s0); the register remains callee-saved.
RVA.1.6	1.2 (p.6)	H	Floating-point Register Convention
RVA.1.7	1.2 (p.6) Table 2	R	Floating-point register convention

Name	ABI Mnemonic	Meaning	Preserved across calls?
f0 - f7	**ft0 - ft7**	Temporary registers	No
f8 - f9	**fs0 - fs1**	Callee-saved registers	Yes*
f10 - f17	**fa0 - fa7**	Argument registers	No
f18 - f27	**fs2 - fs11**	Callee-saved registers	Yes*
f28 - f31	**ft3 - ft11**	Temporary registers	No

* Floating-point values in callee-saved registers are only preserved across calls if they are no larger than the width of a floating-point register in the targeted ABI. Therefore, these registers can always be considered temporaries if targeting the base integer calling convention.

RVA.1.8	1.2 (p.6)	R	The Floating-Point Control and Status Register (fcsr) must have thread storage duration in accordance with C11 section 7.6 "Floating-point environment <fenv.h>".
RVA.1.9	1.3 (p.6)	H	Vector Register Convention

ID	REFERENCE	TYPE	DEFINITION
RVA.1.10	1.3 (p.7) Table 3	R	Vector register convention

Name	ABI Mnemonic	Meaning	Preserved across calls?
v0 - v31		Temporary registers	No
vl		Vector length	No
vtype		Vector data type register	No
vxrm		Vector fixed-point rounding mode register	No
fvxsat		Vector fixed-point saturation flag register	No

RVA.1.11	1.3 (p.7)	R	Vector registers are not used for passing arguments or return values; ...
RVA.1.12	1.3 (p.7)	I	… we intend to define a new calling convention variant to allow that as a future software optimization.
RVA.1.13	1.3 (p.7)	R	The **vxrm** and **vxsat** fields of **vcsr** are not preserved across calls and their values are unspecified upon entry.
RVA.1.14	1.3 (p.7)	R	Procedures may assume that **vstart** is zero upon entry.
RVA.1.15	1.3 (p.7)	R	Procedures may assume that **vstart** is zero upon return from a procedure call.
RVA.1.16	1.3 (p.7)	C	Application software should normally not write **vstart** explicitly. Any procedure that does explicitly write **vstart** to a nonzero value must zero **vstart** before either returning or calling another procedure

CHAPTER 2 Procedure Calling Convention

ID	REFERENCE	TYPE	DEFINITION
RVA.2.1	2.0 (p.8)	H	Procedure Calling Convention
RVA.2.2	2.0 (p.8)	I	This chapter defines standard calling conventions, and describes how to pass parameters and return values.
RVA.2.3	2.0 (p.8)	R	Functions must follow the register convention defined in calling convention: the contents of any register without specifying it as an argument register in the calling convention are unspecified upon entry, and the content of any register without specifying it as a return value register or callee-saved in the calling convention are unspecified upon exit, the contents of all callee-saved registers must be restored to what was set on entry, and the contents of any fixed registers like **gp** and **tp** never change,
RVA.2.4	2.0 (p.8)	C	Calling convention for big-endian is NOT included in this specification yet, we intend to define that in future version of this specification.
RVA.2.5	2.1 (p.8)	H	Integer Calling Convention
RVA.2.6	2.1 (p.8)	R	The base integer calling convention provides eight argument registers, **a0**-**a7**, the first two of which are also used to return values.
RVA.2.7	2.1 (p.8)	R	Scalars that are at most XLEN bits wide are passed in a single argument register, or on the stack by value if none is available.
RVA.2.8	2.1 (p.8)	R	When passed in registers or on the stack, integer scalars narrower than XLEN bits are widened according to the sign of their type up to 32 bits, then sign-extended to XLEN bits.
RVA.2.9	2.1 (p.8)	R	When passed in registers or on the stack, floating-point types narrower than XLEN bits are widened to XLEN bits, with the upper bits undefined.
RVA.2.10	2.1 (p.8)	R	Scalars that are 2×XLEN bits wide are passed in a pair of argument registers, with the low-order XLEN bits in the lower-numbered register and the high-order XLEN bits in the higher-numbered register.
RVA.2.11	2.1 (p.8)	R	(for 2×XLEN bits scalars) If no argument registers are available, the scalar is passed on the stack by value.
RVA.2.12	2.1 (p.8)	R	(for 2×XLEN bits scalars) If exactly one register is available, the low-order XLEN bits are passed in the register and the high-order XLEN bits are passed on the stack.
RVA.2.13	2.1 (p.8)	R	Scalars wider than 2×XLEN bits are passed by reference and are replaced in the argument list with the address.
RVA.2.14	2.1 (p.8)	R	Aggregates whose total size is no more than XLEN bits are passed in a register, with the fields laid out as though they were passed in memory.
RVA.2.15	2.1 (p.8)	R	If no register is available, the aggregate is passed on the stack.
RVA.2.16	2.1 (p.8)	R	Aggregates whose total size is no more than 2×XLEN bits are passed in a pair of registers; if only one register is available, the first XLEN bits are passed in a register and the remaining bits are passed on the stack. If no registers are available, the aggregate is passed on the stack. Bits unused due to padding, and bits past the end of an aggregate whose size in bits is not divisible by XLEN, are undefined.
RVA.2.17	2.1 (p.8)	R	Aggregates or scalars passed on the stack are aligned to the greater of the type alignment and XLEN bits, but never more than the stack alignment.

ID	REFERENCE	TYPE	DEFINITION
RVA.2.18	2.1 (p.8)	R	Aggregates larger than 2×XLEN bits are passed by reference and are replaced in the argument list with the address, as are C++ aggregates with nontrivial copy constructors, destructors, or vtables.
RVA.2.19	2.1 (p.9)	I	Empty structs or union arguments or return values are ignored by C compilers which support them as a non-standard extension. This is not the case for C++, which requires them to be sized types.
RVA.2.20	2.1 (p.9)	R	Bitfields are packed in little-endian fashion.
RVA.2.21	2.1 (p.9)	R	A bitfield that would span the alignment boundary of its integer type is padded to begin at the next alignment boundary.
RVA.2.22	2.1 (p.9)	I	For example, `struct { int x : 10; int y : 12; }` is a 32-bit type with x in bits 9-0, y in bits 21-10, and bits 31-22 undefined. By contrast, `struct { short x : 10; short y : 12; }` is a 32-bit type with x in bits 9-0, y in bits 27-16, and bits 31-28 and bits 15-10 undefined.
RVA.2.23	2.1 (p.9)	R	Bitfields may larger than its integer type, bits excess than its integer type will treat as padding bits, then padding to begin at the next alignment boundary.
RVA.2.24	2.1 (p.9)	I	For example `struct { char x : 9; char y; }` is a 24 byte type with x in bits 7-0, y in bit 23-16, and bits 15-8 undefined, `struct { char x : 9; char y : 2 }` is a 16-bit type with x in bits 7-0, y in bit 10-9, and bit 8, bits 15-11 is undefined.
RVA.2.25	2.1 (p.9)	I	Arguments passed by reference may be modified by the callee.
RVA.2.26	2.1 (p.9)	R	Floating-point reals are passed the same way as aggregates of the same size; complex floating-point numbers are passed the same way as a struct containing two floating-point reals. (This constraint changes when the integer calling convention is augmented by the hardware floating-point calling convention.)
RVA.2.27	2.1 (p.9)	R	In the base integer calling convention, variadic arguments are passed in the same manner as named arguments, with one exception. Variadic arguments with 2×XLEN-bit alignment and size at most 2×XLEN bits are passed in an aligned register pair (i.e., the first register in the pair is even-numbered), or on the stack by value if none is available. After a variadic argument has been passed on the stack, all future arguments will also be passed on the stack (i.e. the last argument register may be left unused due to the aligned register pair rule).
RVA.2.28	2.1 (p.9)	R	Values are returned in the same manner as a first named argument of the same type would be passed. If such an argument would have been passed by reference, the caller allocates memory for the return value, and passes the address as an implicit first parameter.
RVA.2.29	2.1 (p.9)	C	There is no requirement that the address be returned from the function and so software should not assume that a0 will hold the address of the return value on return.
RVA.2.30	2.1 (p.9)	R	The stack grows downwards (towards lower addresses) and the stack pointer shall be aligned to a 128-bit boundary upon procedure entry.
RVA.2.31	2.1 (p.9)	R	The first argument passed on the stack is located at offset zero of the stack pointer on function entry; following arguments are stored at correspondingly higher addresses.
RVA.2.32	2.1 (p.9)	R	In the standard ABI, the stack pointer must remain aligned throughout procedure execution.

ID	REFERENCE	TYPE	DEFINITION
RVA.2.33	2.1 (p.9)	R	Nonstandard ABI code must realign the stack pointer prior to invoking standard ABI procedures.
RVA.2.34	2.1 (p.9)	R	The operating system must realign the stack pointer prior to invoking a signal handler; hence, POSIX signal handlers need not realign the stack pointer.
RVA.2.35	2.1 (p.9)	R	In systems that service interrupts using the interruptee's stack, the interrupt service routine must realign the stack pointer if linked with any code that uses a non-standard stack-alignment discipline, but need not realign the stack pointer if all code adheres to the standard ABI.
RVA.2.36	2.1 (p.10)	R	Procedures must not rely upon the persistence of stack-allocated data whose addresses lie below the stack pointer.
RVA.2.37	2.1 (p.10)	R	Registers **s0**-**s11** shall be preserved across procedure calls.
RVA.2.38	2.1 (p.10)	R	No floating-point registers, if present, are preserved across calls. (This property changes when the integer calling convention is augmented by the hardware floating-point calling convention.)
RVA.2.39	2.2 (p.10)	H	Hardware Floating-point Calling Convention
RVA.2.40	2.2 (p.10)	R	The hardware floating-point calling convention adds eight floating-point argument registers, **fa0**-**fa7**, the first two of which are also used to return values.
RVA.2.41	2.2 (p.10)	R	Values are passed in floating-point registers whenever possible, whether or not the integer registers have been exhausted.
RVA.2.42	2.2 (p.10)	R	The remainder of this section applies only to named arguments. Variadic arguments are passed according to the integer calling convention.
RVA.2.43	2.2 (p.10)	I	ABI_FLEN refers to the width of a floating-point register in the ABI.
RVA.2.44	2.2 (p.10)	R	The ABI_FLEN must be no wider than the ISA's FLEN.
RVA.2.45	2.2 (p.10)	O	The ISA might have wider floating-point registers than the ABI.
RVA.2.46	2.2 (p.10)	I	For the purposes of this section, "struct" refers to a C struct with its hierarchy flattened, including any array fields. That is, `struct { struct { float f[1]; } g[2]; }` and `struct { float f; float g; }` are treated the same.
RVA.2.47	2.2 (p.10)	I	Fields containing empty structs or unions are ignored while flattening, even in C++, unless they have nontrivial copy constructors or destructors.
RVA.2.48	2.2 (p.10)	I	Fields containing zero-length bit-fields are ignored while flattening.
RVA.2.49	2.2 (p.10)	I	Attributes such as aligned or packed do not interfere with a struct's eligibility for being passed in registers according to the rules below, i.e. `struct { int i; double d; }` and `struct __attribute__((__packed__)) { int i; double d }` are treated the same, as are `struct { float f; float g; }` and `struct { float f; float g __attribute__ ((aligned (8))); }`.
RVA.2.50	2.2 (p.10)	R	A real floating-point argument is passed in a floating-point argument register if it is no more than ABI_FLEN bits wide and at least one floating-point argument register is available.
RVA.2.51	2.2 (p.10)	R	Otherwise, it is passed according to the integer calling convention.
RVA.2.52	2.2 (p.10)	R	When a floating-point argument narrower than FLEN bits is passed in a floating-point register, it is 1-extended (NaN-boxed) to FLEN bits.

ID	REFERENCE	TYPE	DEFINITION
RVA.2.53	2.2 (p.10)	R	A struct containing just one floating-point real is passed as though it were a standalone floating-point real.
RVA.2.54	2.2 (p.10)	R	A struct containing two floating-point reals is passed in two floating-point registers, if neither real is more than ABI_FLEN bits wide and at least two floating-point argument registers are available. (The registers need not be an aligned pair.)
RVA.2.55	2.2 (p.10)	R	Otherwise, it is passed according to the integer calling convention.
RVA.2.56	2.2 (p.10)	R	A complex floating-point number, or a struct containing just one complex floating-point number, is passed as though it were a struct containing two floating-point reals.
RVA.2.57	2.2 (p.10)	R	A struct containing one floating-point real and one integer (or bitfield), in either order, is passed in a floating-point register and an integer register, provided the floating-point real is no more than ABI_FLEN bits wide and the integer is no more than XLEN bits wide, and at least one floating-point argument register and at least one integer argument register is available.
RVA.2.58	2.2 (p.10)	R	If the struct is passed in this manner, and the integer is narrower than XLEN bits, the remaining bits are unspecified.
RVA.2.59	2.2 (p.11)	R	If the struct is not passed in this manner, then it is passed according to the integer calling convention.
RVA.2.60	2.2 (p.11)	R	Unions are never flattened and are always passed according to the integer calling convention.
RVA.2.61	2.2 (p.11)	R	Values are returned in the same manner as a first named argument of the same type would be passed.
RVA.2.62	2.2 (p.11)	R	Floating-point registers **fs0**-**fs11** shall be preserved across procedure calls, provided they hold values no more than ABI_FLEN bits wide.
RVA.2.63	2.3 (p.11)	H	ILP32E Calling Convention
RVA.2.64	2.3 (p.11)	C	RV32E is not a ratified base ISA and so we cannot guarantee the stability of ILP32E, in contrast with the rest of this document. This documents the current implementation in GCC as of the time of writing, but may be subject to change.
RVA.2.65	2.3 (p.11)	I	The ILP32E calling convention is designed to be usable with the RV32E ISA.
RVA.2.66	2.3 (p.11)	R	This calling convention is the same as the integer calling convention, except for the following differences. The stack pointer need only be aligned to a 32-bit boundary. Registers **x16**-**x31** do not participate in the calling convention, so there are only six argument registers, **a0**-**a5**, only two callee-saved registers, **s0**-**s1**, and only three temporaries, **t0**-**t2**.
RVA.2.67	2.3 (p.11)	R	If used with an ISA that has any of the registers **x16**-**x31** and **f0**-**f31**, then these registers are considered temporaries.
RVA.2.68	2.3 (p.11)	R	The ILP32E calling convention is not compatible with ISAs that have registers that require load and store alignments of more than 32 bits. In particular, this calling convention must not be used with the D ISA extension.
RVA.2.69	2.4 (p.11)	H	Named ABIs
RVA.2.70	2.4 (p.11)	I	This specification defines the following named ABIs:

ID	REFERENCE	TYPE	DEFINITION
RVA.2.71	2.4 (p.11)	I	ILP32 Integer calling-convention only, hardware floating-point calling convention is not used (i.e. ELFCLASS32 and EF_RISCV_FLOAT_ABI_SOFT).
RVA.2.72	2.4 (p.11)	I	ILP32F ILP32 with hardware floating-point calling convention for ABI_FLEN=32 (i.e. ELFCLASS32 and EF_RISCV_FLOAT_ABI_SINGLE).
RVA.2.73	2.4 (p.11)	I	ILP32D ILP32 with hardware floating-point calling convention for ABI_FLEN=64 (i.e. ELFCLASS32 and EF_RISCV_FLOAT_ABI_DOUBLE).
RVA.2.74	2.4 (p.11)	I	ILP32E ILP32E calling-convention only, hardware floating-point calling convention is not used (i.e. ELFCLASS32, EF_RISCV_FLOAT_ABI_SOFT, and EF_RISCV_RVE).
RVA.2.75	2.4 (p.12)	I	LP64 Integer calling-convention only, hardware floating-point calling convention is not used (i.e. ELFCLASS64 and EF_RISCV_FLOAT_ABI_SOFT).
RVA.2.76	2.4 (p.12)	I	LP64F LP64 with hardware floating-point calling convention for ABI_FLEN=32 (i.e. ELFCLASS64 and EF_RISCV_FLOAT_ABI_SINGLE).
RVA.2.77	2.4 (p.12)	I	LP64D LP64 with hardware floating-point calling convention for ABI_FLEN=64 (i.e. ELFCLASS64 and EF_RISCV_FLOAT_ABI_DOUBLE).
RVA.2.78	2.4 (p.12)	I	LP64Q LP64 with hardware floating-point calling convention for ABI_FLEN=128 (i.e. ELFCLASS64 and EF_RISCV_FLOAT_ABI_QUAD).
RVA.2.79	2.4 (p.12)	R	The ILP32* ABIs are only compatible with RV32* ISAs, and the LP64* ABIs are only compatible with RV64* ISAs.
RVA.2.80	2.4 (p.12)	I	A future version of this specification may define an ILP32 ABI for the RV64 ISA, but currently this is not a supported operating mode.
RVA.2.81	2.4 (p.12)	R	The *F ABIs require the *F ISA extension, the *D ABIs require the *D ISA extension, and the LP64Q ABI requires the Q ISA extension.
RVA.2.82	2.4 (p.12)	C	This means code targeting the Zfinx extension always uses the ILP32, ILP32E or LP64 integer calling-convention only ABIs as there is no dedicated hardware floating-point register file.
RVA.2.83	2.5 (p.11)	H	Default ABIs
RVA.2.84	2.5 (p.11)	R	While various different ABIs are technically possible, for software compatibility reasons it is strongly recommended to use the following default ABIs for specific architectures: on RV32G ILP32D on RV64G LP64D
RVA.2.85	2.5 (p.11)	C	Although RV64GQ systems can technically use LP64Q, it is strongly recommended to use LP64D on general-purpose RV64GQ systems for compatibility with standard RV64G software.

CHAPTER 3 Calling Convention for System Calls

ID	REFERENCE	TYPE	DEFINITION
RVA.3.1	3.0 (p.13)	H	Calling Convention for System Calls
RVA.3.2	3.0 (p.15)	I	The calling convention for system calls does not fall within the scope of this document. Please refer to the documentation of the RISC-V execution environment interface (e.g OS kernel ABI, SBI).

CHAPTER 4 C/C++ type details

ID	REFERENCE	TYPE	DEFINITION
RVA.4.1	4.0 (p.14)	H	C/C++ type details
RVA.4.2	4.1 (p.14)	H	C/C++ type sizes and alignments
RVA.4.3	4.1 (p.14)	I	There are two conventions for C/C++ type sizes and alignments.
RVA.4.4	4.1 (p.14)	H	ILP32, ILP32F, ILP32D, and ILP32E
RVA.4.5	4.1 (p.14) Table 4	R	C/C++ type sizes and alignments for RV32

Type	Size (Bytes)	Alignment (Bytes)
bool/_Bool	**1**	1
char	**1**	1
short	**2**	2
int	**4**	4
long	**4**	4
Long long	**8**	8
void*	**4**	4
_Float16	**2**	2
float	**4**	4
double	**8**	8
Long double	**16**	16
float_complex	**8**	4
double_complex	**16**	8
Long double_complex	**32**	16

RVA.4.6	4.1 (p.14)	H	LP64, LP64F, LP64D, and LP64Q
RVA.4.7	4.1 (p.14) Table 5	I	C/C++ type sizes and alignments for RV64

Type	Size (Bytes)	Alignment (Bytes)
bool/_Bool	**1**	1
char	**1**	1
short	**2**	2
int	**4**	4
long	**8**	8
Long long	**8**	8
__int128	**16**	16
void*	**8**	8
_Float16	**2**	2
float	**4**	4
double	**8**	8
Long double	**16**	16
float_complex	**8**	4
double_complex	**16**	8
Long double_complex	**32**	16

RVA.4.8	4.1 (p.14)	R	The alignment of **max_align_t** is 16 and **CHAR_BIT** is 8.
RVA.4.9	4.1 (p.14)	R	Structs and unions are aligned to the alignment of their most strictly aligned member. The size of any object is a multiple of its alignment.

ID	REFERENCE	TYPE	DEFINITION
RVA.4.10	4.2 (p.14)	H	C/C++ type representations
RVA.4.11	4.2 (p.14)	R	**char** is unsigned.
RVA.4.12	4.2 (p.14)	R	Booleans (bool/_Bool) stored in memory or when being passed as scalar arguments are either 0 (false) or 1 (true).
RVA.4.13	4.2 (p.14)	R	**_Complex** types have the same layout as a struct containing two fields of the corresponding real type (**float**, **double**, or **long double**), with the first member holding the real part and the second member holding the imaginary part.
RVA.4.14	4.3 (p.14)	H	va_list, va_start, and va_arg
RVA.4.15	4.3 (p.14)	R	The va_list type is void*.
RVA.4.16	4.3 (p.14)	R	A callee with variadic arguments is responsible for copying the contents of registers used to pass variadic arguments to the vararg save area, which must be contiguous with arguments passed on the stack.
RVA.4.17	4.3 (p.14)	R	The va_start macro initializes its va_list argument to point to the start of the vararg save area.
RVA.4.18	4.3 (p.14)	R	The va_arg macro will increment its va_list argument according to the size of the given type, taking into account the rules about 2×XLEN aligned arguments being passed in "aligned" register pairs.

Appendix A: Linux-specific ABI

ID	REFERENCE	TYPE	DEFINITION
RVA.A.1	A.0 (p.16)	H	Linux-specific ABI
RVA.A.2	A.0 (p.16)	C	This section of the RISC-V calling convention specification only applies to Linux-based systems.
RVA.A.3	A.0 (p.16)	I	In order to ensure compatibility between different implementations of the C library for Linux, we provide some extra definitions which only apply on those systems. These are noted in this section.
RVA.A.4	A.1 (p.16)	H	Linux-specific C type sizes and alignments
RVA.A.5	A.1 (p.16)	R	The following definitions apply for all ABIs defined in this document. Here there is no differentiation between ILP32 and LP64 ABIs.
RVA.A.6	A.1 (p.16) Table 6	R	Linux-specific C type sizes and alignments

Type	Size (Bytes)	Alignment (Bytes)
wchar_t	**4**	4
wint_t	**4**	4

RVA.A.7	A.2 (p.16)	H	Linux-specific C type representations
RVA.A.8	A.2 (p.16)	R	The following definitions apply for all ABIs defined in this document. Here there is no differentiation between ILP32 and LP64 ABIs.
RVA.A.9	A.2 (p.16)	R	**wchar_t** is signed.
RVA.A.10	A.2 (p.16)	R	**wint_t** is unsigned.

RISC-V ELF Specification

CHAPTER 5 Code models

ID	REFERENCE	TYPE	DEFINITION
RVA.5.1	5.0 (p.18)	H	Code models
RVA.5.2	5.0 (p.18)	I	The RISC-V architecture constrains the addressing of positions in the address space. There is no single instruction that can refer to an arbitrary memory position using a literal as its argument. Rather, instructions exist that, when combined together, can then be used to refer to a memory position via its literal. And, when not, other data structures are used to help the code to address the memory space. The coding conventions governing their use are known as code models.
RVA.5.3	5.0 (p.18)	O	However, some code models can't access the whole address space. The linker may raise an error if it cannot adjust the instructions to access the target address in the current code model.
RVA.5.4	5.1 (p.18)	H	Medium low code model
RVA.5.5	5.1 (p.18)	R	The medium low code model, or **medlow**, allows the code to address the whole RV32 address space or the lower 2 GiB and highest 2 GiB of the RV64 address space (**0xFFFFFFFF7FFF800 ~ 0xFFFFFFFFFFFFFFFF** and **0x0 ~ 0x000000007FFFF7FF**). By using the `lui` and `load` / `store` instructions, when referring to an object, or `addi`, when calculating an address literal, for example, a 32-bit address literal can be produced.

RVA.5.6	5.1 (p.18)	I	The following instructions show how to load a value, store a value, or calculate an address in the **medlow** code model.
			`# Load value from a symbol`
			`lui a0, %hi(symbol)`
			`lw a0, %lo(symbol)(a0)`
			`# Store value to a symbol`
			`lui a0, %hi(symbol)`
			`sw a1, %lo(symbol)(a0)`
			`# Calculate address`
			`lui a0, %hi(symbol)`
			`addi a0, a0, %lo(symbol)`

RVA.5.7	5.1 (p.18)	C	The ranges on RV64 are not **0x0 ~ 0x000000007FFFFFFF** and **0xFFFFFFFF80000000 ~ 0xFFFFFFFFFFFFFFFF** due to RISC-V's sign-extension of immediates; the following code fragments show where the ranges come from:
			`# Largest postive number:`
			`lui a0, 0x7ffff # a0 = 0x7ffff000`
			`addi a0, 0x7ff # a0 = a0 + 2047 = 0x000000007FFFF7FF`
			
			`# Smallest negative number:`
			`lui a0, 0x80000 # a0 = 0xffffffff80000000`
			`addi a0, a0, -0x800 # a0=a0+-2048 =0xFFFFFFFF7FFFF800`

RVA.5.8	5.2 (p.19)	H	Medium any code model

ID	REFERENCE	TYPE	DEFINITION
RVA.5.9	5.2 (p.19)	R	The medium any code model, or **medany**, allows the code to address the range between -2 GiB and +2 GiB from its position. By using `auipc` and `load` / `store` instructions, when referring to an object, or `addi`, when calculating an address literal, for example, a signed 32-bit offset, relative to the value of the pc register, can be produced.
RVA.5.10	5.2 (p.19)	I	As a special edge-case, undefined weak symbols must still be supported, whose addresses will be 0 and may be out of range depending on the address at which the code is linked. Any references to possibly-undefined weak symbols should be made indirectly through the GOT as is used for position-independent code. Not doing so is deprecated and a future version of this specification will require using the GOT, not just advise.
RVA.5.11	5.2 (p.19)	C	This is not yet a requirement as existing toolchains predating this part of the specification do not adhere to this, and without improvements to linker relaxation support doing so would regress performance and code size.

RVA.5.12	5.2 (p.19)	I	The following instructions show how to load a value, store a value, or calculate an address in the medany code model.
			`# Load value from a symbol`
			`.Ltmp0: auipc a0, %pcrel_hi(symbol)`
			`lw a0, %pcrel_lo(.Ltmp0)(a0)`
			`# Store value to a symbol`
			`.Ltmp1: auipc a0, %pcrel_hi(symbol)`
			`sw a1, %pcrel_lo(.Ltmp1)(a0)`
			`# Calculate address`
			`.Ltmp2: auipc a0, %pcrel_hi(symbol)`
			`addi a0, a0, %pcrel_lo(.Ltmp2)`

RVA.5.13	5.2 (p.19)	C	Although the generated code is technically position independent, it's not suitable for ELF shared libraries due to differing symbol interposition rules; for that, please use the medium position independent code model below.
RVA.5.14	5.3 (p.19)	H	Medium position independent code model
RVA.5.15	5.3 (p.19)	R	This model is similar to the medium any code model, but uses the global offset table (GOT) for nonlocal symbol addresses.

RVA.5.16	5.3 (p.19, p.20)	I	(example)
			`#Load value from a local symbol`
			`.Ltmp0: auipc a0, %pcrel_hi(symbol)`
			`lw a0, %pcrel_lo(.Ltmp0)(a0)`
			`# Store value to a local symbol`
			`.Ltmp1: auipc a0, %pcrel_hi(symbol)`
			`sw a1, %pcrel_lo(.Ltmp1)(a0)`
			`# Calculate address of a local symbol`
			`.Ltmp2: auipc a0, %pcrel_hi(symbol)`
			`addi a0, a0, %pcrel_lo(.Ltmp2)`
			`# Calculate address of non-local symbol`
			`.Ltmp3: auipc a0, %got_pcrel_hi(symbol)`
			`l[w|d] a0, a0, %pcrel_lo(.Ltmp3)`

CHAPTER 6 Dynamic Linking

ID	REFERENCE	TYPE	DEFINITION
RVA.6.1	6.0 (p.21)	H	Dynamic Linking
RVA.6.2	6.0 (p.21)	R	Any functions that use registers in a way that is incompatible with the calling convention of the ABI in use must be annotated with STO_RISCV_VARIANT_CC, as defined in Section 8.3.
RVA.6.3	6.0 (p.21)	C	Vector registers have a variable size depending on the hardware implementation and can be quite large. Saving/restoring all these vector arguments in a run-time linker's lazy resolver would use a large amount of stack space and hurt performance. STO_RISCV_VARIANT_CC attribute will require the run-time linker to resolve the symbol directly to prevent saving/restoring any vector registers.

CHAPTER 7 C++ Name Mangling

ID	REFERENCE	TYPE	DEFINITION
RVA.7.1	7.0 (p.22)	H	C++ Name Mangling
RVA.7.2	7.0 (p.22)	R	C++ name mangling for RISC-V follows the *Itanium C++ ABI* †; there are no RISC-V specific mangling rules.
RVA.7.3	7.0 (p.22)	I	See the "Type encodings" section in *Itanium C++ ABI* for more detail on how to mangle types.

† "Itanium C++ ABI" itanium-cxx-abi.github.io/cxx-abi/

CHAPTER 8 ELF Object Files

ID	REFERENCE	TYPE	DEFINITION
RVA.8.1	8.0 (p.23)	H	ELF Object Files
RVA.8.2	8.0 (p.23)	R	The ELF object file format for RISC-V follows the *Generic System V Application Binary Interface* ‡ ("gABI"); this specification only describes RISC-V-specific definitions.
RVA.8.3	8.1 (p.23)	H	File Header
RVA.8.4	8.1 (p.23)	I	The section below lists the defined RISC-V-specific values for several ELF header fields; any fields not listed in this section have no RISC-V-specific values.
RVA.8.5	8.1 (p.23)	R	**e_ident** EI_CLASS Specifies the base ISA, either RV32 or RV64. Linking RV32 and RV64 code together is not supported. ELFCLASS64 ELF-64 Object File ELFCLASS32 ELF-32 Object File EI_DATA Specifies the endianness; either big-endian or little-endian. Linking big-endian and little-endian code together is not supported. ELFDATA2LSB Little-endian Object File ELFDATA2MSB Big-endian Object File
RVA.8.6	8.1 (p.23)	R	**e_machine** Identifies the machine this ELF file targets. Always contains EM_RISCV (243) for RISC-V ELF files.
RVA.8.7	8.1 (p.23) Table 7	R	**e_flags** Describes the format of this ELF file. These flags are used by the linker to disallow linking ELF files with incompatible ABIs together, table below shows the layout of e_flags, and flag details are listed below.

Bit 0	Bits 1-2	Bit 3	Bit 4	Bits 5-23	Bits 24-31
RVC	Float ABI	RVE	TSO	Reserved	Non-standard extensions

RVA.8.8	8.1 (p.23)	R	**EF_RISCV_RVC (0x0001)** This bit is set when the binary targets the C ABI, which allows instructions to be aligned to 16-bit boundaries (the base RV32 and RV64 ISAs only allow 32-bit instruction alignment). When linking objects which specify EF_RISCV_RVC, the linker is permitted to use RVC instructions such as C.JAL in the linker relaxation process.

‡ "Generic System V Application Binary Interface" www.sco.com/developers/gabi/latest/contents.html

ID	REFERENCE	TYPE	DEFINITION
RVA.8.9	8.1 (p.23, p.24)	R	EF_RISCV_FLOAT_ABI_SOFT (0x0000) EF_RISCV_FLOAT_ABI_SINGLE (0x0002) EF_RISCV_FLOAT_ABI_DOUBLE (0x0004) EF_RISCV_FLOAT_ABI_QUAD (0x0006) These flags identify the floating point ABI in use for this ELF file. They store the largest floating-point type that ends up in registers as part of the ABI (but do not control if code generation is allowed to use floating-point internally). The rule is that if you have a floating-point type in a register, then you also have all smaller floating-point types in registers. For example _DOUBLE would store "float" and "double" values in F registers, but would not store "long double" values in F registers. If none of the float ABI flags are set, the object is taken to use the soft-float ABI.
RVA.8.10	8.1 (p.24)	R	EF_RISCV_FLOAT_ABI (0x0006) This macro is used as a mask to test for one of the above floating-point ABIs, e.g., **(e_flags & EF_RISCV_FLOAT_ABI) == EF_RISCV_FLOAT_ABI_DOUBLE**
RVA.8.11	8.1 (p.24)	R	EF_RISCV_RVE (0x0008) This bit is set when the binary targets the E ABI.
RVA.8.12	8.1 (p.24)	R	EF_RISCV_TSO (0x0010) This bit is set when the binary requires the RVTSO memory consistency model.
RVA.8.13	8.1 (p.24)	R	Until such a time that the Reserved bits (`0x00ffffe0`) are allocated by future versions of this specification, they shall not be set by standard software. Non-standard extensions are free to use bits 24-31 for any purpose. This may conflict with other non-standard extensions.
RVA.8.14	8.1 (p.24)	C	There is no provision for compatibility between conflicting uses of the e_flags bits reserved for non-standard extensions, and many standard RISC-V tools will ignore them. Do not use them unless you control both the toolchain and the operating system, and the ABI differences are so significant they cannot be done with a .RISCV.attributes tag nor an ELF note, such as using a different syscall ABI.
RVA.8.15	8.1 (p.24)	H	==== Policy for Merge Objects With Different File Headers
RVA.8.16	8.1 (p.24)	I	This section describe the behavior when the inputs files come with different file headers.
RVA.8.17	8.1 (p.24)	R	**e_ident** and **e_machine** should have exact same value otherwise linker should raise an error.
RVA.8.18	8.1 (p.24)	R	**e_flags** has different different policy for different fields: RVC Input file could have different values for the RVC field; the linker should set this field into EF_RISCV_RVC if any of the input objects has been set.
RVA.8.19	8.1 (p.24)	R	(**e_flags** has different different policy for different fields:) Float ABI Linker should report errors if object files of different value for float ABI field.
RVA.8.20	8.1 (p.25)	R	(**e_flags** has different different policy for different fields:) RVE Linker should report errors if object files of different value for RVE field.
RVA.8.21	8.1 (p.25)	R	(**e_flags** has different different policy for different fields:) TSO Linker should report errors if object files of different value for TSO field.

ID	REFERENCE	TYPE	DEFINITION
RVA.8.22	8.1 (p.25)	C	The static linker may ignore the compatibility checks if all fields in the e_flags are zero and all sections in the input file are non-executable sections.
RVA.8.23	8.2 (p.25)	H	String Tables
RVA.8.24	8.2 (p.25)	R	There are no RISC-V specific definitions relating to ELF string tables.
RVA.8.25	8.3 (p.25)	H	Symbol Table
RVA.8.26	8.3 (p.25)	R	**st_other** The lower 2 bits are used to specify a symbol's visibility. The remaining 6 bits have no defined meaning in the ELF gABI. We use the highest bit to mark functions that do not follow the standard calling convention for the ABI in use.
RVA.8.27	8.3 (p.25) Table 8	R	(**st_other**) The defined processor-specific st_other flags are listed in table below. **Name** | **Mask** STO_RISCV_VARIANT_CC | 0x80 See Chapter 6 for the meaning of STO_RISCV_VARIANT_CC.
RVA.8.28	8.3 (p.25)	R	**__global_pointer$** must be exported in the dynamic symbol table of dynamically-linked executables if there are any GP-relative accesses present in the executable.
RVA.8.29	8.4 (p.25)	H	Relocations
RVA.8.30	8.4 (p.25)	I	RISC-V is a classical RISC architecture that has densely packed non-word sized instruction immediate values. While the linker can make relocations on arbitrary memory locations, many of the RISC-V relocations are designed for use with specific instructions or instruction sequences. RISC-V has several instruction specific encodings for PC-Relative address loading, jumps, branches and the RVC compressed instruction set.
RVA.8.31	8.4 (p.25)	I	The purpose of this section is to describe the RISC-V specific instruction sequences with their associated relocations in addition to the general purpose machine word sized relocations that are used for symbol addresses in the Global Offset Table or DWARF meta data.

ID	REFERENCE	TYPE	DEFINITION
RVA.8.32	8.4 (p.25, p.26)	I	RVA.8.33-RVA.8.39 provides details of the RISC-V ELF relocations; the meaning of each column is given below: **Enum** The number of the relocation, encoded in the r_info field **ELF Reloc Type** The name of the relocation, omitting the prefix of R_RISCV_. **Type** Whether the relocation is a static or dynamic relocation: • A static relocation relocates a location in a relocatable file, processed by a static linker. • A dynamic relocation relocates a location in an executable or shared object, processed by a run-time linker. • Both: Some relocation types are used by both static relocations and dynamic relocations. **Field** Describes the set of bits affected by this relocation; see Section 8.4.2 for the definitions of the individual types **Calculation** Formula for how to resolve the relocation value; definitions of the symbols can be found in Section 8.4.1 **Description** Additional information about the relocation
RVA.8.33	8.4 (p.26) Table 9	R	Relocation types

Enum	ELF Reloc Type	Type	Field / Calculation	Description
0	NONE	None

ID **REFERENCE** **TYPE** **DEFINITION**

RVA.8.43 8.4.1 (p.30) Table 10 R Variables used in relocation calculation

Variable	Description
A	Addend field in the relocation entry associated with the symbol
B	Base address of a shared object loaded into memory
G	Offset of the symbol into the GOT (Global Offset Table)
GOT	Address of the GOT (Global Offset Table)
P	Position of the relocation
S	Value of the symbol in the symbol table
V	Value at the position of the relocation
GP	Value of **__global_pointer$** symbol
TLSMODULE	TLS module index for the object containing the symbol
TLSOFFSET	TLS static block offset (relative to tp) for the object containing the symbol

RVA.8.44 8.4.1 (p.30) R **Global Pointer**: It is assumed that program startup code will load the value of the **__global_pointer$** symbol into register **gp** (aka **x3**).

RVA.8.45 8.4.2 (p.30) H Field Symbols

RVA.8.46 8.4.1 (p.30) Table 11 R Variables used in relocation fields

Variable	Description
word6	Specifies the 6 least significant bits of a *word8* field
word8	Specifies an 8-bit word
word16	Specifies a 16-bit word
word32	Specifies a 32-bit word
word64	Specifies a 64-bit word
wordclass	Specifies a *word32* field for ILP32 or a *word64* field for LP64
B-Type	Specifies a field as the immediate field in a B-type instruction
CB-Type	Specifies a field as the immediate field in a CB-type instruction
CI-Type	Specifies a field as the immediate field in a CI-type instruction
CJ-Type	Specifies a field as the immediate field in a CJ-type instruction
I-Type	Specifies a field as the immediate field in an I-type instruction
S-Type	Specifies a field as the immediate field in an S-type instruction
U-Type	Specifies a field as the immediate field in an U-type instruction
J-Type	Specifies a field as the immediate field in a J-type instruction
U+I-Type	Specifies a field as the immediate fields in a U-type and I-type instruction pair

RVA.8.47 8.4.3 (p.31) H Constants

RVA.8.48 8.4.3 (p.31) Table 12 R Constants used in relocation fields

Name	Value
TLS_DTV_OFFSET	0x800

RVA.8.49 8.4.4 (p.31) H Absolute Addresses

RVA.8.50 8.4.4 (p.31) R 32-bit absolute addresses in position dependent code are loaded with a pair of instructions which have an associated pair of relocations: **R_RISCV_HI20** plus **R_RISCV_LO12_I** or **R_RISCV_LO12_S**.

ID	REFERENCE	TYPE	DEFINITION
RVA.8.51	8.4.4 (p.31)	R	The **R_RISCV_HI20** refers to an `LUI` instruction containing the high 20-bits to be relocated to an absolute symbol address. The `LUI` instruction is used in conjunction with one or more I-Type instructions (add immediate or load) with **R_RISCV_LO12_I** relocations or S-Type instructions (store) with R_RISCV_LO12_S relocations. The addresses for pair of relocations are calculated like this: **HI20 (symbol_address + 0x800) >> 12** **LO12 symbol_address**

RVA.8.52	8.4.4 (p.31)	I	The following assembly and relocations show loading an absolute address:
			`lui a0, %hi(symbol) # R_RISCV_HI20 (symbol)`
			`addi a0, a0, %lo(symbol) # R_RISCV_LO12_I (symbol)`

RVA.8.53	8.4.5 (p.31)	H	Global Offset Table
RVA.8.54	8.4.5 (p.31)	R	For position independent code in dynamically linked objects, each shared object contains a GOT (Global Offset Table), which contains addresses of global symbols (objects and functions) referred to by the dynamically linked shared object.
RVA.8.55	8.4.5 (p.31)	R	The GOT in each shared library is filled in by the dynamic linker during program loading, or on the first call to extern functions.
RVA.8.56	8.4.5 (p.31)	R	To avoid dynamic relocations within the text segment of position independent code the GOT is used for indirection. Instead of code loading virtual addresses directly, as can be done in static code, addresses are loaded from the GOT. This allows runtime binding to external objects and functions at the expense of a slightly higher runtime overhead for access to extern objects and functions.
RVA.8.57	8.4.6 (p.32)	H	Program Linkage Table
RVA.8.58	8.4.6 (p.32)	R	The PLT (Program Linkage Table) exists to allow function calls between dynamically linked shared objects.
RVA.8.59	8.4.6 (p.32)	R	Each dynamic object has its own GOT (Global Offset Table) and PLT (Program Linkage Table).
RVA.8.60	8.4.6 (p.32)	R	The first entry of a shared object PLT is a special entry that calls **_dl_runtime_resolve** to resolve the GOT offset for the called function. The **_dl_runtime_resolve** function in the dynamic loader resolves the GOT offsets lazily on the first call to any function, except when **LD_BIND_NOW** is set in which case the GOT entries are populated by the dynamic linker before the executable is started. Lazy resolution of GOT entries is intended to speed up program loading by deferring symbol resolution to the first time the function is called.

RVA.8.61	8.4.6 (p.32)	I	The first entry in the PLT occupies two 16 byte entries:
			`1: auipc t2, %pcrel_hi(.got.plt)`
			`sub t1, t1, t3 # shifted .got.plt offset+hdr size+12`
			`l[w|d] t3, %pcrel_lo(1b)(t2) # _dl_runtime_resolve`
			`addi t1, t1, -(hdr size+12) # shifted .got.plt offset`
			`addi t0, t2, %pcrel_lo(1b) # &.got.plt`
			`srli t1, t1, log2(16/PTRSIZE) # .got.plt offset`
			`l[w|d] t0, PTRSIZE(t0) # link map`
			`jr t3`

RVA.8.62	8.4.6 (p.32)	R	Subsequent function entry stubs in the PLT take up 16 bytes and load a function pointer from the GOT.

ID	REFERENCE	TYPE	DEFINITION

RVA.8.63	8.4.6 (p.32)	I	On the first call to a function, the entry redirects to the first PLT entry which calls **_dl_runtime_resolve** and fills in the GOT entry for subsequent calls to the function:
			`1: auipc t3, %pcrel_hi(function@.got.plt)`
			`l[w|d] t3, %pcrel_lo(1b)(t3)`
			`jalr t1, t3`
			`nop`

RVA.8.64	8.4.7 (p.32)	H	Procedure Calls
RVA.8.65	8.4.7 (p.32)	R	**R_RISCV_CALL** and **R_RISCV_CALL_PLT** relocations are associated with pairs of instructions (**AUIPC+JALR)** generated by the CALL or TAIL pseudoinstructions. Originally, these relocations had slightly different behavior, but that has turned out to be unnecessary, and they are now interchangeable, **R_RISCV_CALL** is deprecated, suggest using **R_RISCV_CALL_PLT** instead.
RVA.8.66	8.4.7 (p.32)	R	With linker relaxation enabled, the **AUIPC** instruction in the **AUIPC+JALR** pair has both a **R_RISCV_CALL** or **R_RISCV_CALL_PLT** relocation and an **R_RISCV_RELAX** relocation indicating the instruction sequence can be relaxed during linking.
RVA.8.67	8.4.7 (p.32)	R	Procedure call linker relaxation allows the **AUIPC+JALR** pair to be relaxed to the JAL instruction when the procedure or PLT entry is within (-1MiB to +1MiB-2) of the instruction pair.

RVA.8.68	8.4.7 (p.32, p.33)	I	The pseudoinstruction:
			`call symbol`
			`call symbol@plt`
			expands to the following assembly and relocation:
			`# R_RISCV_CALL (symbol), R_RISCV_RELAX (symbol)`
			`auipc ra, 0`
			`jalr ra, ra, 0`
			and when symbol has an **@plt suffix** it expands to:
			`# R_RISCV_CALL_PLT (symbol), R_RISCV_RELAX (symbol)`
			`auipc ra, 0`
			`jalr ra, ra, 0`

RVA.8.69	8.4.8 (p.33)	H	PC-Relative Jumps and Branches
RVA.8.70	8.4.8 (p.33)	R	Unconditional jump (J-Type) instructions have a **R_RISCV_JAL** relocation that can represent an even signed 21-bit offset (-1MiB to +1MiB-2).
RVA.8.71	8.4.8 (p.33)	R	Branch (SB-Type) instructions have a **R_RISCV_BRANCH** relocation that can represent an even signed 13-bit offset (-4096 to +4094).
RVA.8.72	8.4.9 (p.33)	H	PC-Relative Symbol Addresses
RVA.8.73	8.4.9 (p.33)	R	32-bit PC-relative relocations for symbol addresses on sequences of instructions such as the AUIPC+ADDI instruction pair expanded from the la pseudoinstruction, in position independent code typically have an associated pair of relocations: **R_RISCV_PCREL_HI20** plus **R_RISCV_PCREL_LO12_I** or **R_RISCV_PCREL_LO12_S**.
RVA.8.74	8.4.9 (p.33)	R	The **R_RISCV_PCREL_HI20** relocation refers to an **AUIPC** instruction containing the high 20-bits to be relocated to a symbol relative to the program counter address of the **AUIPC** instruction. The **AUIPC** instruction is used in conjunction with one or more I-Type instructions (add immediate or load) with **R_RISCV_PCREL_LO12_I** relocations or S-Type instructions (store) with **R_RISCV_PCREL_LO12_S** relocations.

ID	REFERENCE	TYPE	DEFINITION
RVA.8.75	8.4.9 (p.33)	R	The **R_RISCV_PCREL_LO12_I** or **R_RISCV_PCREL_LO12_S** relocations contain a label pointing to an instruction in the same section with an R_RISCV_PCREL_HI20 relocation entry that points to the target symbol: • At label: **R_RISCV_PCREL_HI20** relocation entry → symbol • **R_RISCV_PCREL_LO12_I** relocation entry → label
RVA.8.76	8.4.9 (p.33, p.34)	R	To get the symbol address to perform the calculation to fill the 12-bit immediate on the add, load or store instruction the linker finds the R_RISCV_PCREL_HI20 relocation entry associated with the AUIPC instruction. The addresses for pair of relocations are calculated like this: **HI20 (symbol_address - hi20_reloc_offset + 0x800) >> 12** **LO12 symbol_address - hi20_reloc_offset**
RVA.8.77	8.4.9 (p.34)	R	The successive instruction has a signed 12-bit immediate so the value of the preceding high 20-bit relocation may have 1 added to it.
RVA.8.78	8.4.9 (p.34)	R	Note the compiler emitted instructions for PC-relative symbol addresses are not necessarily sequential or in pairs. There is a constraint is that the instruction with the **R_RISCV_PCREL_LO12_I** or **R_RISCV_PCREL_LO12_S** relocation label points to a valid HI20 PC-relative relocation pointing to the symbol.

RVA.8.79	8.4.9 (p.34)	I	Here is example assembler showing the relocation types:
			`label:`
			`# R_RISCV_PCREL_HI20 (symbol)`
			`auipc t0, %pcrel_hi(symbol)`
			`lui t1, 1`
			`# R_RISCV_PCREL_LO12_I (label)`
			`lw t2, t0, %pcrel_lo(label)`
			`add t2, t2, t1`
			`# R_RISCV_PCREL_LO12_S (label)`
			`sw t2, t0, %pcrel_lo(label)`

RVA.8.80	8.4.10 (p.34)	H	Relocation for Alignment
RVA.8.81	8.4.10 (p.34)	R	The relocation type **R_RISCV_ALIGN** marks a location that must be aligned to N-bytes, where N is the smallest power of two that is greater than the value of the addend field, e.g. **R_RISCV_ALIGN** with addend value 2 means align to 4 bytes, **R_RISCV_ALIGN** with addend value 4 means align to 8 bytes; this relocation is only required if the containing section has any **R_RISCV_RELAX** relocations, **R_RISCV_ALIGN** points to the beginning of the padding bytes, and the instruction that actually needs to be aligned is located at the point of **R_RISCV_ALIGN** plus its addend.
RVA.8.82	8.4.10 (p.34)	R	To ensure the linker can always satisfy the required alignment solely by deleting bytes, the compiler or assembler must emit a **R_RISCV_ALIGN** relocation and then insert **N** - [IALIGN] padding bytes before the location where we need to align, it could be mark by an alignment directive like **.align**, **.p2align** or **.balign** or emit by compiler directly, the addend value of that relocation is the number of padding bytes.
RVA.8.83	8.4.10 (p.34)	R	The compiler and assembler must ensure padding bytes are valid instructions without any side-effect like **nop** or **c.nop**, and make sure those instructions are aligned to IALIGN if possible.
RVA.8.84	8.4.10 (p.34)	R	The linker may remove part of the padding bytes at the linking process to meet the alignment requirement, and must make sure those padding bytes still are valid instructions and each instruction is aligned to at least **IALIGN** byte.

ID	REFERENCE	TYPE	DEFINITION

RVA.8.85	8.4.10 (p.34)	I	Here is example to showing how **R_RISCV_ALIGN** is used:
			`0x0 c.nop # R_RISCV_ALIGN with addend 2`
			`0x2 add t1, t2, t3 # This inst. must align to 4 byte.`

RVA.8.86	8.4.10 (p.35)	C	**R_RISCV_ALIGN** relocation is needed because linker relaxation can shrink preceding code during the linking process, which may cause an aligned location to become mis-aligned.
RVA.8.87	8.4.10 (p.35)	C	IALIGN means the instruction-address alignment constraint. IALIGN is 4 bytes in the base ISA, but some ISA extensions, including the compressed ISA extension, relax IALIGN to 2 bytes. IALIGN may not take on any value other than 4 or 2. This term is also defined in *The RISC-V Instruction Set Manual* with a similar meaning, the only difference being it is specified in terms of the number of bits instead of the number of bytes.

RVA.8.88	8.4.10 (p.35)	C	Here is pseudocode to decide the alignment of **R_RISCV_ALIGN** relocation:
			`# input:`
			`#  addend: addend value of relocation`
			`#  with R_RISCV_ALIGN type.`
			`# output:`
			`#  Alignment of this relocation.`
			`def align(addend):`
			`ALIGN = 1`
			`while addend >= ALIGN:`
			`ALIGN *= 2`
			`return ALIGN`

RVA.8.89	8.5 (p.35)	H	Thread Local Storage
RVA.8.90	8.5 (p.35)	R	RISC-V adopts the ELF Thread Local Storage Model in which ELF objects define **.tbss** and **.tdata** sections and **PT_TLS** program headers that contain the TLS "initialization images" for new threads.
RVA.8.91	8.5 (p.35)	R	The **.tbss** and **.tdata** sections are not referenced directly like regular segments, rather they are copied or allocated to the thread local storage space of newly created threads. See ELF Handling For Thread-Local Storage **.
RVA.8.92	8.5 (p.35)	R	In The ELF Thread Local Storage Model, TLS offsets are used instead of pointers.
RVA.8.93	8.5 (p.35)	R	The ELF TLS sections are initialization images for the thread local variables of each new thread.
RVA.8.94	8.5 (p.35)	R	A TLS offset defines an offset into the dynamic thread vector which is pointed to by the TCB (Thread Control Block). RISC-V uses Variant I as described by the ELF TLS specification, with **tp** containing the address one past the end of the TCB.
RVA.8.95	8.5 (p.35)	I	There are various thread local storage models for statically allocated or dynamically allocated thread local storage.
RVA.8.96	8.5 (p.35) Table 13	R	Table below lists the thread local storage models:

Mnemonic	Model	TLS LE
Local Exec	TLS IE	Initial Exec
TLS LD	Local Dynamic	TLS GD

** "ELF Handling For Thread-Local Storage" www.akkadia.org/drepper/tls.pdf, Ulrich Drepper

ID	REFERENCE	TYPE	DEFINITION
RVA.8.97	8.5 (p.36)	R	The program linker in the case of static TLS or the dynamic linker in the case of dynamic TLS allocate TLS offsets for storage of thread local variables.
RVA.8.98	8.5 (p.36)	C	**Global Dynamic** model is also known as **General Dynamic** model.
RVA.8.99	8.5.1 (p.36)	H	Local Exec
RVA.8.100	8.5.1 (p.36)	R	Local exec is a form of static thread local storage. This model is used when static linking as the TLS offsets are resolved during program linking.
RVA.8.101	8.5.1 (p.36)	R	Variable attribute **__thread int i __attribute__((tls_model("local-exec")));**

RVA.8.102	8.5.1 (p.36)	I	Example assembler load and store of a thread local variable **i** using the **%tprel_hi, %tprel_add** and **%tprel_lo** assembler functions. The emitted relocations are in comments.
			`# R_RISCV_TPREL_HI20 (symbol)`
			`lui a5,%tprel_hi(i)`
			`# R_RISCV_TPREL_ADD (symbol)`
			`add a5,a5,tp,%tprel_add(i)`
			`# R_RISCV_TPREL_LO12_I (symbol)`
			`lw t0,%tprel_lo(i)(a5)`
			`addi t0,t0,1`
			`# R_RISCV_TPREL_LO12_S (symbol)`
			`sw t0,%tprel_lo(i)(a5)`

RVA.8.103	8.5.1 (p.36)	I	The **%tprel_add** assembler function does not return a value and is used purely to associate the **R_RISCV_TPREL_ADD** relocation with the add instruction.
RVA.8.104	8.5.2 (p.36)	H	Initial Exec
RVA.8.105	8.5.2 (p.36)	I	Initial exec is is a form of static thread local storage that can be used in shared libraries that use thread local storage.
RVA.8.106	8.5.2 (p.36)	R	TLS relocations are performed at load time.
RVA.8.107	8.5.2 (p.36)	I	**dlopen** calls to libraries that use thread local storage may fail when using the initial exec thread local storage model as TLS offsets must all be resolved at load time.
RVA.8.108	8.5.2 (p.36)	R	This model uses the GOT to resolve TLS offsets.
RVA.8.109	8.5.2 (p.36)	R	Variable attribute **__thread int i __attribute__((tls_model("initial-exec")));**
RVA.8.110	8.5.2 (p.36)	R	ELF flags DF_STATIC_TLS

RVA.8.111	8.5.2 (p.36, p.37)	I	Example assembler load and store of a thread local variable **i** using the **la.tls.ie** pseudoinstruction, with the emitted TLS relocations in comments:
			`la.tls.ie a5,i`
			`add a5,a5,tp`
			`lw t0,0(a5)`
			`addi t0,t0,1`
			`sw t0,0(a5)`
			The assembler pseudoinstruction:
			`la.tls.ie a5,symbol`
			expands to the following assembly instructions and relocations:
			`label:`
			`auipc a5, 0 # R_RISCV_TLS_GOT_HI20 (symbol)`
			`{ld,lw} a5, 0(a5) # R_RISCV_PCREL_LO12_I (label)`

ID	REFERENCE	TYPE	DEFINITION
RVA.8.112	8.5.3 (p.37)	H	Global Dynamic
RVA.8.113	8.5.3 (p.37)	I	RISC-V local dynamic and global dynamic TLS models generate equivalent object code.
RVA.8.114	8.5.3 (p.37)	R	The Global dynamic thread local storage model is used for PIC Shared libraries and handles the case where more than one library uses thread local variables, and additionally allows libraries to be loaded and unloaded at runtime using **dlopen**.
RVA.8.115	8.5.3 (p.37)	R	In the global dynamic model, application code calls the dynamic linker function **__tls_get_addr** to locate TLS offsets into the dynamic thread vector at runtime.
RVA.8.116	8.5.3 (p.37)	R	Variable attribute **__thread int i __attribute__((tls_model("global-dynamic")));**

RVA.8.117	8.5.3 (p.37, p.38)	I	Example assembler load and store of a thread local variable **i** using the **la.tls.gd** pseudoinstruction, with the emitted TLS relocations in comments:
			`la.tls.gd a0,i`
			`call __tls_get_addr@plt`
			`mv a5,a0`
			`lw t0,0(a5)`
			`addi t0,t0,1`
			`sw t0,0(a5)`
			The assembler pseudoinstruction:
			`la.tls.gd a0,symbol`
			expands to the following assembly instructions and relocations:
			`label:`
			`auipc a0,0 # R_RISCV_TLS_GD_HI20 (symbol)`
			`addi a0,a0,0 # R_RISCV_PCREL_LO12_I (label)`

RVA.8.118	8.5.3 (p.38)	I	In the Global Dynamic model, the runtime library provides the **__tls_get_addr** function:
			`extern void *__tls_get_addr (tls_index *ti);`
			where the type tls_index is defined as:
			`typedef struct`
			`{`
			`unsigned long int ti_module;`
			`unsigned long int ti_offset;`
			`} tls_index;`

RVA.8.119	8.6 (p.38)	H	Sections
RVA.8.120	8.6.1 (p.38)	H	Section Types
RVA.8.121	8.6.1 (p.38) Table 14	R	The defined processor-specific section types are listed in the table below

Name	Value	Attributes
SHT_RISCV_ATTRIBUTES	0x70000003	none

RVA.8.122	8.6.2 (p.38)	H	Special Sections
RVA.8.123	8.6.2 (p.38) Table 15	R	The table below lists the special sections defined by this ABI.

Name	Type	Attributes
.riscv.attributes	SHT_RISCV_ATTRIBUTES	none

RVA.8.124	8.6.2 (p.38)	R	.riscv.attributes names a section that contains RISC-V ELF attributes.
RVA.8.125	8.7 (p.38)	H	Program Header Table

ID	REFERENCE	TYPE	DEFINITION
RVA.8.126	8.7 (p.38) Table 16	R	The defined processor-specific segment types are listed in the table below

Name	Value	Meaning
PT_RISCV_ATTRIBUTES	0x70000003	RISC-V ELF attribute section.

RVA.8.127	8.7 (p.39)	R	**PT_RISCV_ATTRIBUTES** describes the location of RISC-V ELF attribute section.
RVA.8.128	8.8 (p.39)	H	Note Sections
RVA.8.129	8.8 (p.39)	R	There are no RISC-V specific definitions relating to ELF note sections.
RVA.8.130	8.9 (p.39)	H	Dynamic Section
RVA.8.131	8.9 (p.39) Table 17	R	The defined processor-specific dynamic array tags are listed in the table below

Name	Value	d_un	Executable	Shared Object
DT_RISCV_VARIANT_CC	0x70000001	d_val	Platform specific	Platform specific

RVA.8.132	8.9 (p.39)	R	An object must have the dynamic tag **DT_RISCV_VARIANT_CC** if it has one or more **R_RISCV_JUMP_SLOT** relocations against symbols with the **STO_RISCV_VARIANT_CC** attribute.
RVA.8.133	8.9 (p.39)	R	**DT_INIT** and **DT_FINI** are not required to be supported and should be avoided in favour of **DT_PREINIT_ARRAY**, **DT_INIT_ARRAY** and **DT_FINI_ARRAY**.
RVA.8.134	8.10 (p.39)	H	Hash Table
RVA.8.135	8.10 (p.39)	R	There are no RISC-V specific definitions relating to ELF hash tables.
RVA.8.136	8.11 (p.39)	H	Attributes
RVA.8.137	8.11 (p.39)	I	Attributes are used to record information about an object file/binary that a linker or runtime loader needs to check compatibility.
RVA.8.138	8.11 (p.39)	R	Attributes are encoded in a vendor-specific section of type SHT_RISCV_ATTRIBUTES and name .riscv.attributes.
RVA.8.139	8.11 (p.39)	R	The value of an attribute can hold an integer encoded in the uleb128 format or a null-terminated byte string (NTBS).
RVA.8.140	8.11 (p.39)	R	RISC-V attributes have a string value if the tag number is odd and an integer value if the tag number is even.
RVA.8.141	8.11.1 (p.39)	H	List of attributes

ID	REFERENCE	TYPE	DEFINITION
RVA.8.142	8.11.1 (p.39) Table 18	R	RISC-V attributes

Tag	Value	Parameter Type	Description
Tag_RISCV_stack_align	4	uleb128	Indicates the stack alignment requirement in bytes.
Tag_RISCV_arch	5	NTBS	Indicates the target architecture of this object.
Tag_RISCV_unaligned_access	6	uleb128	Indicates whether to impose unaligned memory accesses in code generation.
Tag_RISCV_priv_spec	8	uleb128	**Deprecated**, indicates the major version of the privileged specification.
Tag_RISCV_priv_spec_minor	10	uleb128	**Deprecated**, indicates the minor version of the privileged specification.
Tag_RISCV_priv_spec_revision	12	uleb128	**Deprecated**, indicates the revision version of the privileged specification.
Reserved for non-standard attribute	>= 32768	-	-

RVA.8.143	8.11.2 (p.39)	H	Detailed attribute description
RVA.8.144	8.11.2 (p.39)	H	How does this specification describe public attributes?
RVA.8.145	8.11.2 (p.39)	R	Each attribute is described in the following structure: **<Tag name>**, **<Value>**, **<Parameter type 1>=<Parameter name 1>**[, **<Parameter type 2>=<Parameter name 2>**]
RVA.8.146	8.11.2 (p.39)	H	Tag_RISCV_stack_align, 4, uleb128=value
RVA.8.147	8.11.2 (p.39)	R	Tag_RISCV_stack_align records the N-byte stack alignment for this object. The default value is 16 for RV32I or RV64I, and 4 for RV32E.
RVA.8.148	8.11.2 (p.39)	R	Merge Policy The linker should report erros if link object files with different **Tag_RISCV_stack_align** values
RVA.8.149	8.11.2 (p.39)	H	Tag_RISCV_arch, 5, NTBS=subarch
RVA.8.150	8.11.2 (p.39)	R	Tag_RISCV_arch contains a string for the target architecture taken from the option **-march**. Different architectures will be integrated into a superset when object files are merged.
RVA.8.151	8.11.2 (p.39)	R	Tag_RISCV_arch should be recorded in lowercase, and all extensions should be separated by underline(_).
RVA.8.152	8.11.2 (p.39)	R	Note that the version information for target architecture must be presented explicitly in the attribute and abbreviations must be expanded.
RVA.8.153	8.11.2 (p.39)	R	The version information, if not given by **-march**, must agree with the default specified by the tool.

ID	REFERENCE	TYPE	DEFINITION
RVA.8.154	8.11.2 (p.39)	I	For example, the architecture **rv32i** has to be recorded in the attribute as **rv32i2p1** in which **2p1** stands for the default version of its based ISA. On the other hand, the architecture **rv32g** has to be presented as `rv32i2p1_m2p0_a2p1_f2p2_d2p2_zicsr2p0_zifencei2p0` in which the abbreviation **g** is expanded to the **imafd_zicsr_zifencei** combination with default versions of the standard extensions.
RVA.8.155	8.11.2 (p.41)	R	The toolchain should normalized the architecture string into canonical order whcih defined in *The RISC-V Instruction Set Manual, Volume I: User-Level ISA, Document* [††], expanded with all required extension and should add shorthand extension into architecture string if all expanded extensions are included in architecture string.
RVA.8.156	8.11.2 (p.41)	C	A shorthand extension is an extension that does not define any actual instructions, registers or behavior, but requires other extensions, such as the **zks** extension, which is defined in the cryptographic extension, **zks** extension is shorthand for **zbkb**, **zbkc**, **zbkx**, **zksed** and **zksh**, so the toolchain should normalize **rv32i_zbkb_zbkc_zbkx_zksed_zksh** to **rv32i_zbkb_zbkc_zbkx_zks_zksed_zksh**; **g** is an exception and does not apply to this rule.
RVA.8.157	8.11.2 (p.39)	R	Merge Policy The linker should merge the different architectures into a superset when object files are merged, and should report errors if the merge result contains conflict extensions. This specification does not mandate rules on how to merge ISA strings that refer to different versions of the same ISA extension. The suggested merge rules are as follows: • Merge versions into the latest version of all input versions that are ratified without warning or error. • The linker should emit a warning or error if input versions have different versions and any extension versions are not ratified. • The linker may report a warning or error if it detects incompatible versions, even if it's ratified.
RVA.8.158	8.11.2 (p.41)	C	Example of conflicting merge result: RV32IF and RV32IZfinx will be merged into RV32IFZfinx, which is an invalid architecture since F and Zfinx conflict.
RVA.8.159	8.11.2 (p.41)	H	Tag_RISCV_unaligned_access, 6, uleb128=value
RVA.8.160	8.11.2 (p.41)	I	Tag_RISCV_unaligned_access denotes the code generation policy for this object file.
RVA.8.161	8.11.2 (p.41)	R	Its values are defined as follows: 0 This object does not perform any unaligned memory accesses. 1 This object may perform unaligned memory accesses.
RVA.8.162	8.11.2 (p.41)	R	Merge policy Input file could have different values for the Tag_RISCV_unaligned_access; the linker should set this field into 1 if any of the input objects has been set.
RVA.8.163	8.11.2 (p.41)	H	Tag_RISCV_priv_spec, 8, uleb128=version
RVA.8.164	8.11.2 (p.41)	H	Tag_RISCV_priv_spec_minor, 10, uleb128=version
RVA.8.165	8.11.2 (p.42)	H	Tag_RISCV_priv_spec_revision, 12, uleb128=version

†† "The RISC-V Instruction Set Manual, Volume I: User-Level ISA, Document", Editors Andrew Waterman and Krste Asanovi´c, RISC-V International.

ID	REFERENCE	TYPE	DEFINITION
RVA.8.166	8.11.2 (p.42)	C	Those three attributes are deprecated since RISC-V using extensions with version rather than a single privileged specification version scheme for privileged ISA.
RVA.8.167	8.11.2 (p.42)	I	Tag_RISCV_priv_spec contains the major/minor/revision version information of the privileged specification.
RVA.8.168	8.11.2 (p.42)	R	Merge policy The linker should report errors if object files of different privileged specification versions are merged.

CHAPTER 9 Linker Relaxation

ID	REFERENCE	TYPE	DEFINITION
RVA.9.1	9.0 (p.43)	H	Linker Relaxation
RVA.9.2	9.0 (p.43)	I	At link time, when all the memory objects have been resolved, the code sequence used to refer to them may be simplified and optimized by the linker by relaxing some assumptions about the memory layout made at compile time.
RVA.9.3	9.0 (p.43)	I	Some relocation types, in certain situations, indicate to the linker where this can happen. Additionally, some relocation types indicate to the linker the associated parts of a code sequence that can be thusly simplified, rather than to instruct the linker how to apply a relocation.
RVA.9.4	9.0 (p.43)	R	The linker should only perform such relaxations when a R_RISCV_RELAX relocation is at the same position as a candidate relocation.
RVA.9.5	9.0 (p.43)	R	As this transformation may delete bytes (and thus invalidate references that are commonly resolved at compile-time, such as intra-function jumps), code generators must in general ensure that relocations are always emitted when relaxation is enabled.
RVA.9.6	9.1 (p.43)	H	Linker Relaxation Types
RVA.9.7	9.1 (p.43)	I	The purpose of this section is to describe all types of linker relaxation, the linker may implement a part of linker relaxation type, and can be skipped the relaxation type is unsupported.
RVA.9.8	9.1 (p.43)	R	Each candidate relocation might fit more than one relaxation type, the linker should only apply one relaxation type.
RVA.9.9	9.1 (p.43)	R	In the linker relaxation optimization, we introduce a concept called relocation group; a relocation group consists of 1) relocations associated with the same target symbol and can be applied with the same relaxation, or 2) relocations with the linkage relationship (e.g. **R_RISCV_PCREL_LO12_S** linked with a **R_RISCV_PCREL_HI20**); all relocations in a single group must be present in the same section, otherwise will split into another relocation group.
RVA.9.10	9.1 (p.43)	R	Every relocation group must apply the same relaxation type, and the linker should not apply linker relaxation to only part of the relocation group.

RVA.9.11	9.1 (p.43)	C	Applying relaxation on the part of the relocation group might result in a wrong execution result; for example, a relocation group consists of
			`lui t0, 0 # R_RISCV_HI20 (foo),`
			`lw t1, 0(t0) # R_RISCV_LO12_I (foo),`
			and we only apply global pointer relaxation on first instruction, then remove that instruction, and didn't apply relaxation on the second instruction, which made the load instruction reference to an unspecified address.

RVA.9.12	9.1.1 (p.43)	H	Function Call Relaxation
RVA.9.13	9.1.1 (p.43)	R	Target Relocation R_RISCV_CALL, R_RISCV_CALL_PLT.
RVA.9.14	9.1.1 (p.43)	R	Description This relaxation type can relax **AUIPC+JALR** into **JAL**.

ID	REFERENCE	TYPE	DEFINITION
RVA.9.15	9.1.1 (p.44)	R	Condition The offset between the location of relocation and target symbol or the PLT stub of the target symbol is within +-1MiB.
RVA.9.16	9.1.1 (p.44)	R	Relaxation • Instruction sequence associated with R_RISCV_CALL or R_RISCV_CALL_PLT can be rewritten to a single JAL instruction with the offset between the location of relocation and target symbol.

RVA.9.17	9.1.1 (p.44)	I	Example
			Relaxation candidate:
			`# R_RISCV_CALL_PLT (symbol), R_RISCV_RELAX`
			`auipc ra, 0`
			`jalr ra, ra, 0`
			Relaxation result:
			`jal ra, 0 # R_RISCV_JAL (symbol)`

RVA.9.18	9.1.1 (p.44)	C	Using address of PLT stubs of the target symbol or address target symbol directly will resolve by linker according to the visibility of the target symbol.
RVA.9.19	9.1.2 (p.44)	H	Compressed Function Call Relaxation
RVA.9.20	9.1.2 (p.44)	R	Target Relocation R_RISCV_CALL, R_RISCV_CALL_PLT.
RVA.9.21	9.1.2 (p.44)	R	Description This relaxation type can relax **AUIPC+JALR** into **C.JAL** instruction sequence.
RVA.9.22	9.1.2 (p.44)	R	Condition The offset between the location of relocation and target symbol or the PLT stub of the target symbol is within +-2KiB and rd operand of second instruction in the instruction sequence is **X1/RA** and if it is RV32.
RVA.9.23	9.1.2 (p.44)	R	Relaxation • Instruction sequence associated with **R_RISCV_CALL** or **R_RISCV_CALL_PLT** can be rewritten to a single **C.JAL** instruction with the offset between the location of relocation and target symbol.

RVA.9.24	9.1.2 (p.44, p.45)	I	Example
			Relaxation candidate:
			`# R_RISCV_CALL_PLT (symbol), R_RISCV_RELAX`
			`auipc ra, 0`
			`jalr ra, ra, 0`
			Relaxation result:
			`c.jal ra, <offset-between-pc-and-symbol>`

RVA.9.25	9.1.3 (p.45)	H	Compressed Tail Call Relaxation
RVA.9.26	9.1.3 (p.45)	R	Target Relocation R_RISCV_CALL, R_RISCV_CALL_PLT.
RVA.9.27	9.1.3 (p.45)	R	Description This relaxation type can relax **AUIPC+JALR** into **C.J** instruction sequence.
RVA.9.28	9.1.3 (p.45)	R	Condition The offset between the location of relocation and target symbol or the PLT stub of the target symbol is within +-2KiB and rd operand of second instruction in the instruction sequence is **X0**.

ID	REFERENCE	TYPE	DEFINITION
RVA.9.29	9.1.3 (p.45)	R	Relaxation • Instruction sequence associated with **R_RISCV_CALL** or **R_RISCV_CALL_PLT** can be rewritten to a single **C.J** instruction with the offset between the location of relocation and target symbol.

RVA.9.30	9.1.3 (p.45)	I	Example
			Relaxation candidate:
			`# R_RISCV_CALL_PLT (symbol), R_RISCV_RELAX`
			`auipc ra, 0`
			`jalr x0, ra, 0`
			Relaxation result:
			`c.j ra, <offset-between-pc-and-symbol>`

RVA.9.31	9.1.4 (p.45)	H	Global-pointer Relaxation
RVA.9.32	9.1.4 (p.45)	R	Target Relocation R_RISCV_HI20, R_RISCV_LO12_I, R_RISCV_LO12_S, R_RISCV_PCREL_HI20, R_RISCV_PCREL_LO12_I, R_RISCV_PCREL_LO12_S
RVA.9.33	9.1.4 (p.45)	R	Description This relaxation type can relax a sequence of the load address of a symbol or load/store with a symbol reference into global-pointer-relative instruction.
RVA.9.34	9.1.4 (p.45, p.46)	R	Condition Offset between global-pointer and symbol is within +-2KiB, **R_RISCV_PCREL_LO12_I** and **R_RISCV_PCREL_LO12_S** resolved as indirect relocation pointer. It will always point to another **R_RISCV_PCREL_HI20** relocation, the symbol pointed by **R_RISCV_PCREL_HI20** will be used in the offset calculation.
RVA.9.35	9.1.4 (p.46)	R	Relaxation • Instruction associated with **R_RISCV_HI20** or **R_RISCV_PCREL_HI20** can be removed. • Instruction associated with **R_RISCV_LO12_I**, **R_RISCV_LO12_S**, **R_RISCV_PCREL_LO12_I** or **R_RISCV_PCREL_LO12_S** can be replaced with a global-pointer-relative access instruction.

RVA.9.36	9.1.4 (p.46)	I	Example
			Relaxation candidate:
			`# R_RISCV_HI20 (symbol), R_RISCV_RELAX`
			`lui t0, 0`
			`# R_RISCV_LO12_I (symbol), R_RISCV_RELAX`
			`lw t1, 0(t0)`
			Relaxation result:
			`lw t1, <gp-offset-for-symbol>(gp)`

RVA.9.37	9.1.4 (p.46)	C	The global-pointer refers to the address of the **__global_pointer$** symbol, which is the content of **gp** register.

ID	REFERENCE	TYPE	DEFINITION

RVA.9.38	9.1.4 (p.46)	C	This relaxation requires the program to initialize the **gp** register with the address of **__global_pointer$** symbol before accessing any symbol address, strongly recommended initialize **gp** at the beginning of the program entry function like **_start**, and code fragments of initialization must disable linker relaxation to prevent initialization instruction relaxed into a NOP-like instruction (e.g. **mv gp, gp**).
			
			`# Recommended way to initialize the gp register.`
			`.option push`
			`.option norelax`
			`1: auipc gp, %pcrel_hi(__global_pointer$)`
			`addi gp, gp, %pcrel_lo(1b)`
			`.option pop`

RVA.9.39	9.1.4 (p.46)	C	The global pointer is referred to as the global offset table pointer in many other targets, however, RISC-V uses PC-relative addressing rather than access GOT via the global pointer register (**gp**), so we use **gp** register to optimize code size and performance of the symbol accessing.
RVA.9.40	9.1.5 (p.46)	H	Zero-page Relaxation
RVA.9.41	9.1.5 (p.46)	R	Target Relocation R_RISCV_HI20, R_RISCV_LO12_I, R_RISCV_LO12_S
RVA.9.42	9.1.5 (p.47)	R	Description This relaxation type can relax a sequence of the load address of a symbol or load/store with a symbol reference into shorter instruction sequence if possible.
RVA.9.43	9.1.5 (p.47)	R	Condition The symbol address located within **0x0** ~ **0x7ff** or **0xfffffffffffff800** ~ **0xffffffffffffffff** for RV64 and **0xfffff800** ~ **0xffffffff** for RV32.
RVA.9.44	9.1.5 (p.47)	R	Relaxation • Instruction associated with **R_RISCV_HI20** can be removed if the symbol address satisfies the x0-relative access. • Instruction associated with **R_RISCV_LO12_I** or **R_RISCV_LO12_S** can be relaxed into x0-relative access.

RVA.9.45	9.1.5 (p.47)	I	Example
			Relaxation candidate:
			`lui t0, 0 # R_RISCV_HI20 (symbol), R_RISCV_RELAX`
			`lw t1, 0(t0) # R_RISCV_LO12_I (symbol), R_RISCV_RELAX`
			Relaxation result:
			`lw t1, <address-of-symbol>(x0)`

RVA.9.46	9.1.6 (p.47)	R	Compressed LUI Relaxation
RVA.9.47	9.1.6 (p.47)	R	Target Relocation R_RISCV_HI20, R_RISCV_LO12_I, R_RISCV_LO12_S
RVA.9.48	9.1.6 (p.47)	R	Description This relaxation type can relax a sequence of the load address of a symbol or load/store with a symbol reference into shorter instruction sequence if possible.
RVA.9.49	9.1.6 (p.47)	R	Condition The symbol address can be presented by a **C.LUI** plus an **ADDI** or load / store instruction.

ID	REFERENCE	TYPE	DEFINITION
RVA.9.50	9.1.6 (p.47)	R	Relaxation • Instruction associated with **R_RISCV_HI20** can be replaced with **C.LUI**. • Instruction associated with **R_RISCV_LO12_I** or **R_RISCV_LO12_S** should keep unchanged.

RVA.9.51	9.1.6 (p.47, p.48)	I	Example
			Relaxation candidate:
			`lui t0, 0 # R_RISCV_HI20 (symbol), R_RISCV_RELAX`
			`lw t1, 0(t0) # R_RISCV_LO12_I (symbol), R_RISCV_RELAX`
			Relaxation result:
			`c.lui t0, <non-zero> #RVC_LUI (symbol), R_RISCV_RELAX`
			`lw t1, 0(t0) # R_RISCV_LO12_I (symbol), R_RISCV_RELAX`

RVA.9.52	9.1.7 (p.48)	H	Thread-pointer Relaxation
RVA.9.53	9.1.7 (p.48)	R	Target Relocation R_RISCV_TPREL_HI20, R_RISCV_TPREL_ADD, R_RISCV_TPREL_LO12_I, R_RISCV_TPREL_LO12_S.
RVA.9.54	9.1.7 (p.48)	R	Description This relaxation type can relax a sequence of the load address of a symbol or load/store with a thread-local symbol reference into a thread-pointer-relative instruction.
RVA.9.55	9.1.7 (p.48)	R	Condition Offset between thread-pointer and thread-local symbol is within +-2KiB.
RVA.9.56	9.1.7 (p.48)	R	Relaxation • Instruction associated with **R_RISCV_TPREL_HI20** or **R_RISCV_TPREL_ADD** can be removed. • Instruction associated with **R_RISCV_TPREL_LO12_I** or **R_RISCV_TPREL_LO12_S** can be replaced with a thread-pointer-relative access instruction.

RVA.9.57	9.1.7 (p.48)	I	Example
			Relaxation candidate:
			`# R_RISCV_TPREL_HI20 (symbol), R_RISCV_RELAX`
			`lui t0, 0`
			`# R_RISCV_TPREL_ADD (symbol), R_RISCV_RELAX`
			`add t0, t0, tp`
			`# R_RISCV_TPREL_LO12_I (symbol), R_RISCV_RELAX`
			`lw t1, 0(t0)`
			Relaxation result:
			`lw t1, <tp-offset-for-symbol>(tp)`

RISC-V DWARF Specification

CHAPTER 10 DWARF Debugging Format

ID	REFERENCE	TYPE	DEFINITION
RVA.10.1	10.0 (p.51)	H	DWARF Debugging Format
RVA.10.2	10.0 (p.51)	I	The DWARF debugging format for RISC-V follows the standard DWARF specification‡‡; this specification only describes RISC-V-specific definitions.

‡‡ https://dwarfstd.org/

CHAPTER 11 DWARF Register Numbers

ID	REFERENCE	TYPE	DEFINITION
RVA.11.1	11.0 (p.52)	H	DWARF Register Numbers
RVA.11.2	11.0 (p.52) Table 19	R	The table below lists the mapping from DWARF register numbers to machine registers

TagDWARF Number	Register Name	Description
0 - 31	x0 - x31	Integer Registers
32 - 63	f0 - f31	Floating-point Registers
64		Alternate Frame Return Column
65 - 95		Reserved for future standard extensions
96 - 127	v0 - v31	Vector Registers
128 - 3071		Reserved for future standard extensions
3072 - 4095		Reserved for custom extensions
4096 - 8191		CSRs

RVA.11.3	11.0 (p.52)	R	The alternate frame return column is meant to be used when unwinding from signal handlers, and stores the address where the signal handler will return to.
RVA.11.4	11.0 (p.52)	R	The RISC-V specification defines a total of 4096 CSRs[§§]. Each CSR is assigned a DWARF register number corresponding to its specified CSR number plus 4096.

§§ "The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Document", Editors Andrew Waterman, Krste Asanovi´c, and John Hauser, RISC-V International.
